

**WATER RESOURCES
OF THE
SHOALHAVEN VALLEY**

**SURVEY OF THIRTY N.S.W. RIVER VALLEYS
REPORT NO 8 — OCTOBER 1967**

WATER RESOURCES OF THE SHOALHAVEN RIVER VALLEY

PREFACE

BY THE HON. JACK G. BEALE, M.E., A.S.T.C. Mech. Eng.,
M.I.E. Aust., M.ASCE., M.A.S.M.E., M.A.S.A.E., M.L.A.
MINISTER FOR CONSERVATION
NEW SOUTH WALES

In accordance with the policy of the New South Wales Liberal-Country Party Government announced prior to the May, 1965 State Elections, I directed the Water Conservation and Irrigation Commission of New South Wales to undertake a comprehensive valley survey of the State's water resources as a prerequisite to the formulation of a balanced and soundly-based programme of water conservation.

The survey will be the largest and most comprehensive study of water resources ever undertaken in Australia. It will embrace thirty major river valleys of the State and will cover all the main aspects of their physiography, climate and water resources - both surface and underground - together with a review of current and possible future water requirements.

As it will be some time before the whole survey can be completed, separate reports are being issued for the individual river valleys. This report on the Water Resources of the Shoalhaven River Valley is the eighth report to be completed.

JACK G. BEALE. M.L.A.

October, 1967.

WATER RESOURCES OF THE SHOALHAVEN RIVER VALLEY

1. INTRODUCTION.

Man is dependent on reliable and adequate water supplies, not only for agricultural and industrial development, but for his very existence.

About three quarters of the Earth's surface is permanently covered by water in the oceans and polar ice caps, the remaining quarter comprising the land masses. The total volume of water on Earth, in all its forms, has been estimated to be about 320 million cubic miles. However, it is difficult to adequately relate the magnitude of this volume to other natural resources, particularly when it is considered that one cubic mile is equivalent to about a million million gallons.

Obviously the usefulness of this resource is most limited as about 97.2 percent is in the oceans and a further 2 percent is held in the polar icecaps. In addition, as underground water comprises over 99.5 percent of the remaining 0.8 percent, the amount of fresh water contained in lakes and streams approximates to only 0.004 percent of the total volume of water on Earth.

In an effort to ensure that adequate water supplies would be available, early civilizations established their villages near major rivers and, mainly because of the limited amounts of water needed, supplies were generally adequate. However the water requirements of modern civilizations are of such magnitudes that it is normally not possible to satisfy major industrial or large area irrigation demands in the absence of large water conservation dams on the streams.

Modern society makes huge demands on water supplies for domestic, industrial and agricultural purposes. In the production of a ton of paper about 60 tons of water are used; a ton of steel requires about 300 tons of water and a ton of food requires about 1,000 tons of water.

Annual water requirements of crops are usually of the order of two to three feet depth and during a drought period it is necessary to provide a major proportion of this requirement by irrigation. The relative magnitude of this demand can be assessed when it is realised that a depth of three feet over an area of only one acre is equivalent to over 800,000 gallons.

The gross water resources of any country are usually considered to be the total amount of precipitation, comprised of rainfall or snow, which falls on the land. The surface water resources are usually regarded as the amounts of water in rivers and lakes.

In comparison with all of the other continents, Australia has the least average annual precipitation, the average rainfall being only about $1\frac{1}{2}$ feet whereas Africa, Asia, Europe and North America all receive about 2 feet and South America receives an average of almost $4\frac{1}{2}$ feet.

However, when losses, due to the natural processes of evaporation, transpiration and seepage are deducted from the average rainfalls of the continents, the residuals, or surface water resources, show that Australia has a comparative runoff much less than indicated by the average rainfalls. The average annual surface water resources of the Australian mainland have been assessed at about 240 million acre feet which is equivalent to a depth of less than 2 inches over the continental area. In comparison, runoffs for the other continents are about 7 inches in Africa, 9 inches in Asia and Europe, 11 inches in North America and about 19 inches in South America.

Due to the relatively flat topography of the Australian continent, there are no areas that are permanently covered by snow and as a result, streamflows in Australia are largely dependent upon the occurrence of runoff producing storms. Australian streams therefore tend to exhibit greater variability in flow than those of other continents.

The extreme variability of flows in the majority of Australian streams and the prolonged duration of severe droughts makes it imperative that water conservation dams be constructed if assured water supplies are to be maintained over the full period of each drought.

The surface water resources of the Shoalhaven River Valley have been assessed as averaging about 1,460,000 acre feet per annum. As the average annual rainfall over the valley is 35 inches, the surface water resources are equivalent to a runoff of about 28 percent.

On a square mile basis, the surface water resources of the Shoalhaven River Valley are about $1\frac{1}{3}$ times the average for coastal basins in New South Wales and over five times the average for the total area of the State.

2. PHYSIOGRAPHIC FEATURES.

The extent of the Shoalhaven River Valley, as adopted for the purposes of this report, is shown at Figure 1; the total area of the valley is about 2,820 square miles.

The headwaters of the Shoalhaven River rise in the extreme south of the valley in mountainous country in the vicinity of the Eurambene and Bald Mountains, the latter being over 4,800 feet in elevation. The river flows almost due north to near Majors Creek, being joined on the left bank by Jinden and Jerrabattgulla Creeks both of which rise in rugged country to the west of the Shoalhaven River. Notable peaks in the Jerrabattgulla Creek catchment are The Bald Peak and Mount Cowangerong, both of which are about 4,500 feet in elevation.

Below Majors Creek the Shoalhaven River sweeps generally to the north-east and is joined by Jembaicumbene and Gillamatong Creeks on the right bank and Reedy and Boro Creeks on the left bank. The town of Braidwood is located on Gillamatong Creek about five miles upstream of the Shoalhaven River Junction.

The western boundary of the Shoalhaven River Valley is formed by the Great Dividing Range and whilst steep land slopes prevail along the boundary to the south-west of Braidwood, the divide in the section from Mount Fairy to near Goulburn is characterised by relatively flat slopes and is ill-defined.

About sixteen miles to the north of Braidwood the Shoalhaven River is joined by a major tributary, the Mongarlowe River, which rises near Sugarloaf Mountain in the Budawang Range. The Mongarlowe River travels a distance of about twenty five miles in a northerly direction and passes through Monga and Mongarlowe before turning to the north-west and joining the Shoalhaven River about sixteen miles north of Braidwood. The catchment of the Mongarlowe River is comprised of mountainous topography in the upper sections along the eastern boundary, and undulating to hilly land forms in the lower section near the Shoalhaven River.

The Corang River rises in the Budawang Range in the vicinity of The Peak (elevation 2,800 feet) and joins the Shoalhaven River about three miles west of Nerriga. Below Nerriga, the Shoalhaven River is joined on the right bank by another major tributary, the Endrick River, which rises in the Budawang Range in mountainous terrain and features a number of waterfalls in its course to the main river valley.

Above Welcome Reef the Shoalhaven River passes through generally undulating country; however, from Welcome Reef where the river enters a narrow gorge to a point about four miles west of Nowra, it travels through mountainous country.

Nerrimunga Creek, a left bank tributary of the Shoalhaven River, rises in hilly country to the east of Lake Bathurst and enters a steep sided gorge before joining the Shoalhaven River about five miles downstream of the Endrick River. Bungonia Creek commences in hilly to steep terrain about ten miles east of Goulburn and passes through Bungonia before entering a canyon which extends almost to the junction of the creek and the Shoalhaven River. Barbers Creek rises in undulating country near Tallong and, in similar fashion to Bungonia Creek, enters a steep gorge before joining the Shoalhaven River about one mile downstream of the Bungonia Creek junction.

The southern tributaries of the Shoalhaven River downstream of the Endrick River drain a large plateau area bounded by the Turpentine Range on the south-east. The majority of defined streams in this area commence on the relatively flat plateau and fall over the escarpment edge into steep sided valleys. The four main streams in this area are Ettrema, Bundundah, Danjera and Yarramunmun Creeks all of which drain into Yalwal Creek which joins the Shoalhaven River about twelve miles west of Nowra.

The remaining major tributary of the Shoalhaven River is the Kangaroo River, the upper tributaries of which rise in the Robertson - Moss Vale plateau. This river travels generally in a westerly direction over a distance of about thirty miles before joining the Shoalhaven River some twenty miles upstream of Nowra. Whilst the Kangaroo River traverses rugged mountainous terrain and waterfalls for parts of its length, there are limited areas of alluvial flats which are used for dairying. About two miles upstream of the Kangaroo - Shoalhaven River junction the Kangaroo River is joined by Bundanoon Creek on its right bank. This creek commences in undulating country near Bundanoon and, in common with the streams in this area, drops rapidly into a steep sided valley in its lower reaches.

About ten miles upstream of Nowra the Shoalhaven River emerges onto a plain and from Burrier to the mouth flows through increasingly wide alluvial flats. The alluvial flats extend northwards up the valley of Broughton Creek to the town of Berry and southwards to the vicinity of Jervis Bay.

In the lower Shoalhaven Valley dairying is the principal agricultural industry; the dairying area extending from the upper reaches of Broughton Creek over the alluvial flats south-east of Nowra. The main secondary agricultural industry in this section of the valley is the growing of fodder, such as maize, lucerne and oats.

Land use in the upper Shoalhaven Valley is mainly confined to the grazing of sheep for wool and, where suitable areas occur, for the production of fat lambs. In some minor areas of the upper valley cattle grazing is the predominant industry.

Many sections of the valley, particularly in the dissected plateau area west of Nowra are uninhabited and largely unused for any type of agricultural pursuit.

Land slopes in the Shoalhaven River Valley are shown at Figure 2. The flat areas in the valley, with slopes less than 3 degrees, are very limited and comprise only 8 percent of the total valley area. Undulating to hilly land forms, with slopes between about 3 and 8 degrees, predominate and occur over nearly half of the valley (44 percent of the total area). Hilly to steep areas (slopes between 8 degrees and 15 degrees) make up a further 17 percent of the valley while the remaining 31 percent is comprised of mountainous sections with slopes greater than 15 degrees.

3. CLIMATIC FEATURES.

Rainfall.

The distribution of rainfall over the Shoalhaven River Valley is controlled to a large extent by orographic effects, rainfall in general increasing with increasing elevation. Annual median rainfalls of the order of 60 inches are found over the high ground which forms the headwaters of the Kangaroo River in the vicinity of Robertson. (The median is that rainfall equalled or exceeded on fifty percent of occasions).

Another high rainfall area exists over the range which separates the valleys of the Clyde and upper Shoalhaven Rivers, the annual median rainfall reaching a maximum of about 50 inches over the higher slopes east of Braidwood. To the west of this high rainfall area a marked rain shadow exists, annual median rainfalls decreasing to less than 25 inches. Along the coastal plain the annual median rainfall varies between about 35 and 45 inches.

The distribution of annual median rainfall over the catchment is shown at Figure 3 whilst the distribution of monthly median rainfalls are shown at Figures 4 to 15 inclusive.

In general, the spatial distribution of monthly rainfall throughout the area is similar to the annual rainfall distribution. Although the region lies in latitudes in which the distribution of rainfall throughout the year would be expected to be uniform, in general higher monthly rainfall is experienced in the months December to April when about 50 percent of the annual amount is received. In the period August to November inclusive only about 25 percent of the annual amount is generally received.

The Australian Alps shelter the region from most south to west airstreams which are the predominant rain producing airstreams over southern New South Wales in the winter and spring months. May, June and July each receive about 8 percent of the annual rainfall while August is the driest month on the average receiving about 5 percent of the annual rainfall.

In August median rainfalls vary from about 2 to 2½ inches over the higher rainfall areas to less than 1 inch in the rain shadow areas.

The wettest month varies from station to station in the valley but occurs in one of the months from January to April inclusive. The wettest month median values vary from 3½ to 4½ inches over the high rainfall areas to less than 2 inches over the rain shadow area.

Monthly and annual rainfalls recorded at Bateman's Bay, Berry, Braidwood, Bundanoon, Bungonia, Jervis Bay, Krawarree, Lower Boro, Milton, Mount Fairy, Nowra and Robertson are given in Appendices 1 to 12 respectively.

Very heavy storm rainfalls may occur over the valley when an active depression is centred off the New South Wales coast just north of the valley. Storms of this type affect the area on an average of about twice a year and they may occur in any month of the year. The highest falls on record for a 24 hour period ending 9 a.m. are 20.83 inches on 13th January 1911 and 20.05 inches on 14th February 1898 at Brogers Creek.

Monthly totals of more than 20 inches have been recorded at all stations except those lying in the rain shadow along the upper valley. In this area highest monthly totals vary from 13 to 17 inches. Notably high monthly totals are 47.4 inches at Araluen, just outside the boundary of the valley and 42.5 inches at Robertson which were recorded in May 1925 and May 1943 respectively.

The tables at Appendix 13 show on a monthly and annual basis for Bateman's Bay, Berry, Braidwood, Bundanoon, Bungonia, Jervis Bay, Krawarree, Lower Boro, Milton, Mount Fairy, Nowra and Robertson the following data:

- (1) The maximum and minimum rainfall totals on record.
- (2) The 10th, 30th, 50th, 70th and 90th percentiles.

(A rainfall observation less than the 10th percentile value can be expected once every ten years on the average. Similarly, a rainfall observation less than the 70th percentile can be expected in seven years out of ten or alternatively a rainfall observation greater than the 70th percentile can be expected on an average of three years in ten).

Minimum rainfalls recorded at Bateman's Bay, Berry, Braidwood, Bundanoon, Jervis Bay and Nowra are shown in the tables at Appendix 14. The tables indicate the minimum cumulative rainfall commencing in any month of the year and continuing for up to 12 months, which have occurred at these stations.

Although very low rainfall totals have been recorded for a few consecutive months, prolonged dry spells are infrequent, particularly on the coast and over the higher rainfall areas. Except for the rainshadow area, at least $7\frac{1}{2}$ inches are received on 90 percent of occasions in any consecutive six month period. The corresponding figure for any consecutive 12 month period is $17\frac{1}{2}$ inches.

Temperature.

The temperature regime of the valley is reasonably well recorded. The average monthly and yearly temperatures for available stations are listed in Tables 1 to 4 as follows:

Tables 1 and 2 Jervis Bay and Wollongong respectively, which may be taken as representative of the immediate coastal area of the valley.

Table 3 Nowra which is representative of locations on the coastal plain inland from the sea.

Table 4 Braidwood, representative of the areas of the valley about 2,500 feet above sea level.

Highest on Record											Lowest on Record 14.5		

During the months October to March, warm weather is experienced with average maxima varying from the mid seventies to the low eighties over the lower parts of the valley away from the coast. Somewhat cooler conditions occur over the higher parts of the valley and also on the coast where sea breezes tend to reduce maximum temperatures. Days are mild to cool for the remainder of the year except over the more elevated areas during the winter months where days are rather cold.

Occasionally very hot days are experienced in summer when dry north westerly winds blow from Central Australia. Wollongong has experienced an extreme temperature of 115° F. On the average, temperatures above 100° F are recorded about twice per year on the coast. A greater frequency of occurrence would be expected over low level areas inland.

On the coast average minima are about 10° F to 15° F cooler than corresponding maxima. Inland, however, ranges of 20° F or more may occur. In winter on occasions of clear skies and light winds very low overnight temperatures occur particularly at the higher stations of the region. At Braidwood, an extreme minimum temperature of 14.5° F has been recorded.

Frost.

Frost incidence increases from almost nil on the coast to more than 90 days per year over the higher parts of the hinterland where frosts can occur at any time of the year. Severe frosts, however, are usually confined to the months April to October inclusive in the highest areas with the season becoming shorter at lower elevations.

Sunshine.

Estimates of the average number of hours of bright sunshine per day in each month for the valley are shown in Table 5. These estimates are based on cloud amount observations.

TABLE 5

Estimated Average Daily Duration of Bright Sunshine
(Hours)

Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year
8.1	7.8	7.1	6.7	6.1	5.8	6.5	6.9	7.7	8.0	8.3	8.2	7.3

Evaporation.

Estimates of the average monthly and annual evaporation from an Australian standard sunken tank are shown in Table 6 together with estimates of the standard deviations. These estimates are based on radiation, air temperature and humidity considerations.

TABLE 6

Estimated Average Monthly and Annual Evaporation
(Inches)

Month	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year
Evaporation	5.5	4.2	3.8	2.6	1.8	1.4	1.6	1.6	2.4	3.5	5.1	5.5	39.0
Standard Deviation	0.9	0.9	0.7	0.4	0.4	0.3	0.3	0.3	0.4	0.5	0.7	0.8	3.0

Wind.

Strong winds and squalls occur over the region from time to time in association with meteorological conditions as follows:

1. Easterly to southerly winds with mean speeds of up to 50 miles per hour and gusts up to 70 miles per hour or more may occur on the coast when a deep depression is located just off the southern New South Wales or eastern Victorian coast.
2. Strong north to north-west winds with mean wind speeds of the order of 50 miles per hour with gusts on occasions reaching 70 miles per hour have been recorded at Port Kembla as the pressure gradient tightens ahead of an approaching southerly change. Similar winds would be expected to occur over the Shoalhaven Valley particularly on the coast.

3. The highest wind gusts on record in the valley are associated with severe local squalls such as thunderstorms or frontal squalls.

Table 7 gives the extreme wind gust likely to be experienced in the valley for various return periods.

TABLE 7

Estimated Extreme Wind Gusts to be Expected for Given Return Periods.

Return Period (Years)	10	20	50	100
Extreme Wind Gust Equalled or Exceeded (Miles Per Hour)	85	90	100	105

4. GROUNDWATER POTENTIAL.

Like many of the coastal rivers of New South Wales the catchment of the Shoalhaven River provides convincing evidence of earth movements in Tertiary time which raised most of the valley several thousand feet.

The greater part of the valley comprises portion of the Southern Tablelands; the original gradients, and to some extent the mature form of the valleys of the main stream and many of its tributaries, are still maintained upstream of a series of waterfalls, by which the streams leave the plateau. After plunging into deep gorges they flow through rugged country before the main valley opens out and river flats of relatively recent age appear on the inside of the entrenched meanders.

In the vicinity of Nowra the broad alluvial plains commence and continue almost to the sea, where there are raised beaches and wind blown sands along the coastline.

The geological map at Figure 16 shows the area to be geologically complex, particularly in the southern and western parts, where a considerable variety of older Palaeozoic strata (Ordovician, Silurian and Devonian) occur, including greywackes, slates, quartzites, sandstones, shales, siltstones, limestones and interbedded volcanics. These ancient rocks have been strongly folded and faulted, and invaded by granites and allied intrusions believed to be of Devonian and Carboniferous age.

The northern and eastern parts of the valley are underlain by more recent strata which comprise the southern section of the Sydney Basin. These Permian and Mesozoic strata include mainly shales, sandstones and conglomerates with some contemporaneous volcanic rocks.

There are remnants of Tertiary river deposits on the Tableland, some of which are capped by basalt of Late Tertiary age. Pleistocene and Recent alluvia occur in some of the upland valleys and flank the Shoalhaven River in its lower reaches. There are sand beds on the north side of the mouth of the Shoalhaven River which extend some miles to the north behind Seven Mile Beach.

Discussion of the groundwater potential of this valley is facilitated if three main subdivisions, based on the mode of occurrence of the water and the nature of the strata in which it is stored, are used; viz. Jointed Rocks, which although themselves impervious, may contain water in the partings, fractures, bedding planes, joint systems etc; Porous Rocks, usually sandstones, which may contain water in openings between cemented sand grains; and Unconsolidated Deposits, in which water may be stored in the pore spaces in sands and/or gravels associated with alluvial material, or in accumulations of aeolian and beach sands near the coast.

In the Shoalhaven River Valley, groundwater is utilized mainly for watering stock, whilst irrigation from this source is the exception rather than the rule. Records of bores in the valley are relatively few, but are sufficient to indicate that the general groundwater potential of the area for stock watering facilities is good but that the potential for irrigation is poor.

Jointed Rocks.

With the exception of those parts of the valley underlain by the Hawkesbury Sandstone and the alluvial and beach sand deposits, the Shoalhaven River catchment is underlain by strata in which the groundwater is contained in cracks, fissures, partings and joints in the rocks. Included in this group are a variety of metamorphic rocks, indurated sedimentary strata and plutonic and volcanic igneous rocks. The water bearing potential of this group varies considerably, the outcome of boring for water depending on many factors

including the rock type, the degree of weathering and jointing, the relative elevation and relief at the bore site, the amount and distribution of the rainfall, and the ability of the rain to percolate through the soils which have been produced by the local environment.

The oldest strata in this group are of Ordovician age (more than 400 million years old) which include mainly greywacke, chert, slate, quartzite, sandstone and limestone. Dips vary over a wide range, but the strike is usually north-north-west. Faulting is common and there is a tendency for the harder, more resistant strata (greywacke, chert and quartzite in particular) to be heavily fractured. It is in these rocks that conditions favourable to the occurrence of groundwater are to be expected, although less competent strata such as slates may also yield useful supplies of water.

Bores in these strata, located at favourable sites, can usually be relied on to yield useful supplies of stock water. Yields of 300 to 400 gallons per hour are likely and in some instances (although none have been recorded in this valley) supplies greatly exceeding 1,000 gallons per hour have been obtained from such strata.

The salinity of the waters varies, it being usual for higher yielding bores to produce better quality water. Total salinities range from about 50 to 300 parts per hundred thousand, with the sodium chloride content ranging up to 200 parts per hundred thousand. The waters are fairly hard, and even where the Total Salinity is low, softening is usually required to make the water suitable for domestic use.

Most failures in these strata can be attributed to either poor sites or failure to bore deep enough into the sometimes rather hard strata.

The Silurian strata outcrop in several meridionally disposed zones in the western part of the valley. They include slates, phyllites and limestones comprising a sequence of metamorphic rocks and a series of volcanic rocks. Overlying them and the older Ordovician there are a number of formations of Upper Devonian age which include similar rock sequences to the Silurian; volcanic rocks are interbedded with sedimentary beds, which have been less metamorphosed than the older strata and are best described as meta-sediments.

However both systems of rocks have lost any original porosity they may have possessed (except the limestones which in some areas e.g. near Bungonia, are cavernous), and hence they are included with the jointed rocks.

The outcome of boring in these strata is essentially the same as in the Ordovician rocks where useful stock supplies are normally obtainable at selected sites, with occasional yields in excess of 1,000 gallons per hour of "good" quality water. The salinity limits also are essentially the same, although "salty" springs which have been observed issuing from some small outcrops of Devonian strata north of Bungonia (the outcrops are too small to appear on the map) suggest that in the Devonian shales there is a higher saline content in the contained groundwater than is the case in the harder strata.

Permian rocks underlie most of the eastern part of the Shoalhaven River Valley. Once again the sequence contains sedimentary and volcanic rocks including conglomerates, sandstones, siltstones, shales, tuffs, lavas, cherts and coal seams. The sediments have been indurated and are largely impervious except for joints, partings and other secondary openings.

The Megalong Conglomerate which outcrops over extensive areas to the west and south of Nowra contains conglomerates, sandstones and siltstones which have been little prospected for groundwater in this valley. However the occasional bore in this and nearby catchments suggests that useful supplies of fair to good quality groundwater can be expected from bores from 50 to 200 feet deep.

The overlying Berry Formation which includes a large proportion of shales and siltstones has not proved a reliable water-bearing formation, supplies ranging from less than 100 gallons per hour to as much as 3,000 gallons per hour being recorded. The few analyses available show the salinity of groundwater from the Berry shales to be quite low, a Total Saline content less than 100 parts per hundred thousand being usual. A bore in the township of Berry which penetrated 85 feet of shale yielded 600 gallons per hour for a drawdown of only 8 feet of the available 74 feet. The analysis of water from this bore shows a Total Salinity of 32 parts per hundred thousand, Alkalinity (as Sodium Carbonate) 18 parts per hundred thousand, Hardness (as Calcium Carbonate) 10 parts per hundred thousand and pH 6.6.

The Gerringong Volcanics, which include some thick, well jointed tuffaceous sandstones have produced some surprisingly high yields. A number of bores less than 100 feet deep located in the vicinity of Gerringong yield supplies well in excess of 1,000 gallons per hour, one bore being equipped to produce 6,000 gallons per hour for irrigation. Water from this bore has a Total Saline content of 144 parts per hundred thousand, a Hardness of 80 parts per hundred thousand and a pH of 6.8.

An unusually high yielding bore in this sequence is located only a few miles west of Gerringong. It encountered heavily jointed tuffaceous sandstones at 166 feet from which a large flow of about 40,000 gallons per hour was obtained. The driller who constructed this bore reported that blocks of sandstone of housebrick size were brought to the surface by the great velocity of the water. An analysis of this water shows: Total Salinity 61.9 parts per hundred thousand; Hardness (as Calcium Carbonate) 30.8 parts per hundred thousand and pH 7.7. The considerable head of water encountered in this bore probably results from an intake in the higher country to the west.

The Illawarra Coal Measures are much more important for their coal content than for their groundwater potential. As far as is known there are no bores in this valley producing water from these strata, but it is known that they normally yield brackish water in other parts of the Sydney Basin.

The granites, which form the backbone of the Great Dividing Range some 4,000 feet high in the south-western part of the valley, and also outcrop over considerable areas near Braidwood and Bungonia, are expected to be useful water bearers only where they are deeply weathered. However there are no records of bores in them, although it is known that springs are fairly common in the general vicinity of Braidwood.

A well twenty two feet deep, located near Majors Creek yielded 100 gallons per hour from the weathered granite and it is considered that relatively small supplies suitable for stock watering should be obtainable from bores on satisfactory sites. In areas of high relief, such as are found near the western divide, the depth of weathering is unlikely to be sufficient to provide worthwhile supplies of groundwater and the limited amount of jointing found in granites suggests that boring in them would be speculative. Some small but valuable supplies are obtained from springs, which are fairly common.

Basalts of Tertiary age form some small cappings in rough country east of Lower Boro, but the major outcrops are confined to the area forming the divide east from Robertson. It is in the larger outcrops of basalt that the best groundwater prospects are expected.

Bores at good sites can be expected to yield supplies suitable for stock watering and, after softening, for domestic use. Recorded yields range from 200 to 1,000 gallons per hour and in most instances the water has proved suitable for garden use. The analysis of a water sample from a bore of depth 80 feet in basalt in the vicinity of the headwaters of Bundanoon Creek shows a Total Saline content of 40.9 parts per hundred thousand, Alkali (as Sodium Carbonate) 14.3 parts per hundred thousand, Hardness (as Calcium Carbonate) 10 parts per hundred thousand and pH 4.4.

Porous Rocks.

The Triassic strata which comprise part of the southern end of the Sydney Basin contain the only rocks in this group from which useful supplies of groundwater are obtained.

Of them, the Lower Triassic Narrabeen group which consists of clayey sandstones, silts and shales, have only a small area of outcrop, the main exposures being along the flanks of the Moss Vale - Robertson plateau. The strata are relatively impervious and in this area have no significant groundwater potential.

The overlying Hawkesbury Sandstones, which are well exposed in the vertical cliffs flanking the valleys of Bundanoon Creek and the Kangaroo River, underlie most of the plateau occupying the northern edge of the Shoalhaven River Valley and outcrop over much of it. Cappings of the Wianamatta group obscure them in the more elevated parts and there are also some extensive areas of basalt near Robertson and Moss Vale.

The Hawkesbury Sandstones have a maximum thickness of about 800 feet but usually they contain only a few relatively thin porous zones. However in this southern part of the Sydney Basin the zones are thicker and more persistent than elsewhere.

Most bores constructed entirely in these sandstones yield supplies of the order of 800 to 1,000 gallons per hour of water with a salinity less than 10 parts per hundred thousand. A number of aquifers are encountered, the yield from each successively deeper aquifer usually being greater than the one above.

A bore near Fitzroy Falls is typical of the conditions in this sandstone formation. Strata penetrated are sandstones of various colours, white, yellow and pale grey being the most common. Aquifers occurred at 27 - 30 feet, 101 - 108 feet and 167 - 182 feet, the respective supplies being 20, 180 and 630 gallons per hour; at 630 gallons per hour only one third of the available drawdown was utilized, indicating that a supply of about 1,200 gallons per hour could be obtained.

A partial analysis of the water from this bore gave: Total Salinity of 6.4 parts per hundred thousand; Chloride (as Sodium Chloride 2 parts per hundred thousand and pH 5.8. The low salinity and somewhat acid pH are typical of the waters from the Hawkesbury Sandstone where they are not influenced by the overlying Wianamatta group which consists essentially of shales with occasional thin beds of sandstone.

As is the case elsewhere in the Sydney Basin, the Wianamatta group almost invariably yields saline waters which are usually suitable only for stock, and are rarely suitable for watering even very salt tolerant plant life. The saline water from the shales is believed to be responsible for the poorer than usual quality of the water in the upper aquifers of Hawkesbury Sandstone where they underlie and are close to shale outcrops. In cases where bores penetrate an appreciable thickness of the Wianamatta Shales it may be necessary to cement off the shallower aquifers in order to prevent contamination of the better quality water which can usually be obtained by boring several hundred feet into the Hawkesbury Sandstones.

Unconsolidated Material.

There are two distinct generations of alluvium in the Southern Tablelands, the first being probably of Tertiary age whilst the second is believed to have been deposited during the Pleistocene period.

The actual base of the Tertiary alluvium is often as much as 100 feet above the present stream beds, these clays, sands and gravels having been built up by ancestral streams prior to the uplift of the tablelands. Occasionally these ancient gravels have been silicified into "silcrete", possibly due to contact metamorphism by basalts which have since been removed by erosion.

Because of their elevation the sands and gravels in the Tertiary alluvium are of little or no importance as a source of groundwater.

The distribution of the Pleistocene (and possibly more recent) alluvium on the Tablelands suggests that there has been some late or post Tertiary movement along some of the numerous faults. The geological map (Figure 16) shows some extensive areas of alluvium in the valley of the main stream to the north and west of Braidwood and also in some of the tributary valleys.

As far as is known no bores have been constructed in these areas, but adjacent catchments indicate there may be over 200 feet of alluvial material with some thin but extensive beds of sand and gravel beneath the larger flats. Large yields are not anticipated but supplies of several thousand gallons per hour of good quality water appear possible in some areas. It is believed that the more recent alluvium on the smaller tributaries is not more than 30 or 40 feet thick, but it seems likely that suitably sited wells or bores would yield useful supplies of stock water and perhaps limited irrigation supplies.

After the main river leaves the plateau it flows through a deep gorge, and there is no alluvial development of any consequence until the valley slowly begins to open out downstream of its confluence with the Kangaroo River. Here some narrow flats occur on the inside of the entrenched meanders. These isolated flats are believed to be of fluviatile origin, and it is considered that there would be little difficulty in obtaining supplies for stock purposes from either bores or wells at depths between 20 and 50 feet.

For some 10 or 12 miles upstream of Nowra the river is tidal and the alluvium is of estuarine origin, having been deposited in a brackish or salt water environment. There is a considerable thickness of this usually dark coloured, silty and muddy alluvium. Test boring carried out by the Metropolitan Water Sewerage and Drainage Board at the downstream end of Long Reach (a few miles upstream of Nowra) encountered 180 feet of mud, silt and sand without reaching bedrock, and seismic surveys indicate a maximum thickness of the order of 300 feet of salt water charged sediments. In the vicinity of Nowra the river leaves its confined valley and flows across an extensive alluvial plain which is underlain by deltaic deposits, chiefly black sands silts and muds with occasional bands of material containing shells of marine origin. Much of the area is low lying and swampy.

As is the case elsewhere along the coast, most of the groundwater stored in this alluvium is either brackish or salty, and the occasional supply of good quality water is the result of especially favourable conditions, such as may be found in the levees or in areas where sands occur at, or very close to, the surface. In both cases direct infiltration of local rainfall forms a lens of fresh water which displaces the brackish or saline water and virtually "floats" on the more dense, salty water. In such conditions good quality water rarely extends below 20 - 25 feet from the surface, after which any bore or well is likely to encounter brackish or salty water.

The levees offer the best prospects for useful supplies of groundwater, and wells or spearpoints located on them usually produce water suitable for stock, domestic and garden use, although the yields are very variable, ranging from a few hundred to more than one thousand gallons per hour.

Away from the levees there is a fairly rapid deterioration in the water quality so that shallow supplies are usually suitable only for stock watering. During dry periods the water table may fall several feet and there is often a corresponding increase in the salinity of the shallow groundwater. However runoff from the side slopes will sometimes result in the occurrence of localized zones of good quality water. Such a zone occurs on the north side of the Shoalhaven River in an area near Meroo, which is located towards the edge of the alluvial plain between Nowra and Berry.

There is a considerable development of alluvial flats on Broughton Creek, and upstream of Berry the water table is known to be shallow, and the quality of the water good. Although there are no records of wells in this alluvium being used to supply water for irrigation it seems likely that sufficient water could be obtained for this purpose from suitable wells. Downstream of Berry, where the Broughton Creek flats merge with those of the Shoalhaven River, the environment at the time of deposition was estuarine, and hence the prospects of obtaining good quality water are believed to be similar to those on the main flats, (i.e. chiefly brackish to saline water with occasional lenses of better quality water).

To the north of the mouth of the Shoalhaven River there is an extensive area of aeolian and beach sands which runs parallel to Seven Mile Beach for a width of about three quarters of a mile. Behind the beach there are low lying swampy areas which contain accumulations of decayed vegetable matter. This

environment is typical of the conditions under which the sands have accumulated, and is responsible for peaty and acid groundwater which is often encountered in areas of beach sands.

Utilization of the water from these sands is confined to camping grounds, caravan parks and occasional domestic supplies which are usually obtained from spearpoints not more than 15 feet deep. It is probable that supplies suitable for irrigation could be obtained from bores or batteries of spearpoints in these sands, but the poor soils which occur in the beach sand areas are likely to restrict this type of development.

Although there are probably two or three square miles of these sand beds which would yield water of low salinity suitable for town or industrial water supplies, the elongated shape of the area would make large scale extraction of water from the area quite costly. If this were practicable, it may well be possible to obtain several million gallons per day of water (possibly requiring treatment by aeration and limedosing) from this source.

5. STREAM GAUGING STATIONS.

Streamflow originates in the precipitation of atmospheric moisture which is mainly evaporated from the oceans and is carried over the land masses by weather systems. Runoff is generally recognised to be that component of precipitation which appears as flow in streams after evaporation, transpiration and deep seepage losses have been satisfied.

In most areas of New South Wales rainfall records have been obtained for relatively long periods of time. Therefore, it could be expected that if satisfactory estimates were able to be made of losses due to evaporation, transpiration and deep seepage the remainder of the precipitation, or runoff, could be reliably assessed. However, despite intensive research, no suitable method has yet been formulated of relating runoff and rainfall for any catchment to a satisfactory degree of accuracy in the absence of any stream flow information.

In water resources and other hydrologic investigations it is therefore essential to have basic streamflow data available in order to enable satisfactory results and conclusions to be obtained. In addition it is most desirable that these streamflow records cover as long a period as possible.

Two basic steps are involved in streamflow measurement, the first being the measurement of river level, or gauge height, in relation to a constant datum and the second being the correlation of measured height with stream discharge.

River heights are normally obtained by visual observation of the level of the water surface on a graduated scale, or staff gauge, which is installed on the river bank or on bridge piers. However these measurements only indicate the water level at the time of observation and therefore it is desirable to record the continuous variation of river levels between the times of actual readings. This may be effected by means of a continuous graphical or digital record which is produced by a float or pressure actuated recorder.

Measurements of stream discharge are made by use of a current meter to measure flow velocities, and survey methods to measure the area of effective flow. The combination of flow velocities, in feet per second, and effective areas, in square feet, gives the discharge of the stream in cubic feet per second or cusecs.

Relations are established, by means of graphs, between gauge heights and corresponding discharges based on all streamflow measurements at the gauging station and, in stable channels, these relations tend to remain relatively constant. The relationships are employed to estimate stream discharges for periods when gauge heights, but not measured flows, are available for the station. It is therefore possible to derive continuous streamflow records at any station using gauge height data and the gauge height - discharge relationship.

Stream discharges are normally given in terms of cusecs, one cusec flowing for twelve hours being approximately equal to one acre foot or the volume of water which would cover an area of one acre to a depth of one foot. An additional unit which is frequently used in catchment yield studies is inches depth over the total catchment area.

The installation of stream gauging stations in the Shoalhaven River Valley commenced with the erection of a station at Welcome Reef in 1909. Additional stations were installed on the Shoalhaven River at Warri in 1914 and on both the Corang and Mongarlowe Rivers at Hockeys and Charleyong respectively in 1924.

At present there are eight stream gauging stations in the valley which are operated by the Water Conservation and Irrigation Commission. In addition the Metropolitan Water Sewerage and Drainage Board is currently operating seven permanent and six temporary gauging stations but only limited periods of records are available for these stations.

Due to the short periods of record available for the Board's stream gauging stations flow statistics represent only a small sample of flow regimes and therefore are unlikely to be indicative of long term flow conditions. Details of statistics for the Board's stream gauging stations have therefore not been included in the tables of flow statistics given later in this report.

The current gauging stations are situated so as to measure the runoff from about ninety percent of the Shoalhaven River Valley. The density of permanent streamflow stations in the Shoalhaven River Valley of about five stations per thousand square miles, is slightly more than the density for Coastal New South Wales and is substantially greater than the New South Wales and Australian averages of 2.2 stations and 0.5 stations respectively.

Some difficulties have been experienced in maintaining continuous operation of stream gauging stations in the valley. These difficulties stem from the sparse distribution of population over the valley particularly in the rugged, relatively inaccessible, areas of high runoff. As a result, seven stream gauging stations, installed at various times from 1924, have had to be discontinued, due mainly to unavailability of gauge readers.

The locations of existing and discontinued gauging stations in the Shoalhaven River Valley are shown in Figure 17 and relevant operational details of each station are given in Table 8.

6. CATCHMENT YIELDS.

The systematic and regular recording of streamflow in the Shoalhaven River Valley has provided a substantial volume of hydrologic data for estimation of water yield from the various sections of the valley. The water yield, or runoff, from a natural catchment is dependent on many factors, the main ones being annual rainfall, catchment area, topography and geology. In addition other factors which control the runoff resulting from a particular storm are rainfall intensity, vegetal cover and soil moisture conditions.

Over the sixteen year period commencing in 1950 the average discharge of the Mongarlowe River at Mongarlowe was 86,600 acre feet per annum which is equivalent to an average flow of 119 cusecs (44,400 gallons per minute). At the gauging station located on the Mongarlowe River at Marlowe the average flow

over a twenty one year period has been 173,000 acre feet per annum (237 cusecs). However, this latter station measures runoff from a catchment area of more than three times that above Mongarlowe, and therefore these yields are consistent with hydrologic principles.

At the Corang River at Hockeys the average annual flow over a forty two year period was 58,100 acre feet (80 cusecs) or about 30,000 gallons per minute. Over the period of available record of thirteen years the discharge of the Endrick River at Nowra Road has been about 105,000 acre feet per annum (143 cusecs) or about 54,000 gallons per minute.

Records of streamflow for the Kangaroo River at Kangaroo Valley indicate that the average annual runoff at this station over a nine year period was 227,000 acre feet (310 cusecs) or 116,000 gallons per minute.

Over a thirty two year period the flow of the Shoalhaven River at Warri was 171,000 acre feet per annum (234 cusecs). At Welcome Reef on the Shoalhaven River the average discharge over a fifty two year period of record was 467,000 acre feet per annum (640 cusecs).

For comparative purposes the yields at various streamflow stations, over the respective periods of available records are given in Table 9. Details of monthly maximum, minimum and mean flows for the gauging stations located on the Mongarlowe River at Marlowe, the Shoalhaven River at Welcome Reef, the Corang River at Hockeys, the Endrick River at Nowra Road and the Kangaroo River at Kangaroo Valley are given in Appendices 15 to 19 inclusive.

TABLE 9.

Stream	Station	Years of Complete Records	Average Annual Yield Over Period of Complete Years of Record		
			Acre Feet Per Annum	Cusecs	Gallons Per Minute
Mongarlowe River	Mongarlowe	17	84,000	115	43,000
Mongarlowe River	Marlowe	21	173,000	237	89,000
Corang River	Hockeys	42	58,100	80	30,000
Endrick River	Nowra Road	13	105,000	143	54,000
Kangaroo River	Kangaroo Valley	9	227,000	310	116,000
Shoalhaven River	Warri	32	171,000	234	88,000
Shoalhaven River	Welcome Reef	52	467,000	640	240,000

7. AVERAGE ANNUAL RUNOFF.

Based on the streamflow records available for the Shoalhaven River at Welcome Reef, over the period from 1909 to date, estimates have been prepared of the long term average annual runoffs of selected sub-catchments in the Shoalhaven River Valley.

These estimates indicate that the average annual surface water resources of the Shoalhaven River Valley are of the order of 1,460,000 acre feet (396,000 million gallons) which is equivalent to a continuous rate of 750,000 gallons per minute. On a square mile of catchment area basis this runoff is more than one third greater than the average for coastal basins in New South Wales and over five times the average for the State.

In the following Table 10 the estimated long term average annual runoff of the Shoalhaven River Valley is compared with the corresponding runoffs for the Hawkesbury and Bega Valleys.

TABLE 10.

Basin	Catchment Area in Square Miles	Estimated Long Term Average Annual Runoff		
		Acre Feet per Annum	Acre Feet per Annum per square mile	Percentage Runoff
Shoalhaven Valley	2,820	1,460,000	520	28%
Hawkesbury Valley	8,390	1,850,000	220	11%
Bega Valley	740	400,000	540	27%

A previous estimate of the long term average annual runoff for the Shoalhaven River Valley was given in the 1963 publication "Review of Australia's Water Resources" as 1,230,000 acre feet per annum. This estimate was based on periods of records of 46 years at Welcome Reef as compared with the 52 years now available.

The average annual runoff of the Shoalhaven River Valley is equivalent to about 28 percent of the annual rainfall over the valley and, when compared with other adjacent valleys, this percentage is comparatively high.

However, the high estimated runoff of the Shoalhaven River Valley is attributable to the high yielding areas in the north of the valley where consistently high rainfalls occur.

The percentage runoff for the adjacent Hawkesbury River Valley, (given in Table 10), of 11 percent appears to be relatively low when compared with the Shoalhaven River Valley. However, the runoff from a catchment tends to decrease with increase in area and as the Hawkesbury River catchment is about three times that of the Shoalhaven River the percentage runoffs are compatible.

8. VARIABILITY OF STREAMFLOWS.

Whilst average annual discharges are commonly used for the comparison of long term yields from a catchment they do not indicate the variability of flows from year to year. The variability of annual flows from a catchment is of utmost importance in the planning of water resources projects; the greater the variability, the more difficult it is to economically utilise the available surface water resources of a valley.

In common with the majority of other streams in New South Wales the streams in the Shoalhaven River Valley exhibit a high degree of variability. An indication of the variability of streamflows at selected stations in the valley is given in Table 11. This table indicates the maximum, minimum and mean discharges recorded at the stations over the periods of available records.

TABLE 11

Stream	Station	Period of Computed Records	Recorded Discharge		
			Maximum	Minimum	Mean
Mongarlowe River	Marlowe	August 1945 to June 1967	47,200 cusecs (17,700,000 g.p.m.)	2 cusecs (750 g.p.m.)	237 cusecs (89,000 g.p.m.)
Corang River	Hockeys	September 1924 to June 1967	34,700 cusecs (13,000,000 g.p.m.)	0	80 cusecs (30,000 g.p.m.)
Endrick River	Nowra Road	July 1953 to June 1967	28,000 cusecs (10,500,000 g.p.m.)	0	143 cusecs (54,000 g.p.m.)
Kangaroo River	Kangaroo Valley	July 1954 to June 1967	81,000 cusecs (30,300,000 g.p.m.)	0.7 cusecs (260 g.p.m.)	310 cusecs (116,000 g.p.m.)
Shoalhaven River	Welcome Reef	June 1909 to June 1967	313,000 cusecs (117,000,000 g.p.m.)	0	640 cusecs (240,000 g.p.m.)

Available streamflow records indicate that there is a high degree of variability in the annual water resources of the Shoalhaven River Valley. On the Shoalhaven River at Welcome Reef the maximum annual discharge occurred in 1950 and was nearly two million acre feet or over four times the average annual discharge. As the minimum annual discharge at this location was about 38,000 acre feet, the ratio of maximum annual to minimum annual flow was in excess of fifty to one.

The maximum monthly flow recorded at Welcome Reef was nearly 900,000 acre feet in May 1925 which is equivalent to more than twenty times the average monthly flow. During the month of January 1919, no flow was recorded at this station for the entire month.

On both the Corang River at Hockeys and the Mongarlowe River at Marlowe the maximum recorded annual discharge was about $2\frac{1}{2}$ times the mean annual flow. The minimum annual flows at these stations were only about 10 percent of the mean.

The recorded maximum and minimum annual discharges of the Kangaroo River at Kangaroo Valley were about double, and one quarter respectively of the mean flow.

The monthly variations in streamflows always exhibit a greater variability than annual discharges, the maximum monthly flows at Nowra Road, Marlowe and Hockeys being seven, ten and twenty three times the respective mean monthly flows.

Histograms of monthly streamflows recorded at the stream gauging stations at Welcome Reef, Marlowe, Hockeys, Nowra Road and Kangaroo Valley are shown in Figures 18 to 20 inclusive; these Figures illustrate the high degree of variability of streamflows in the valley. Furthermore examination of Figures 18 to 20 indicates that no apparent periodic trend occurs in runoff.

The mean monthly rainfalls in the valley are relatively uniformly distributed throughout the year. The mean monthly rainfall at Braidwood varies from about $2\frac{1}{2}$ inches in the summer months from December to March inclusive to about 2 inches in the months from July to September. A similar pattern in average monthly rainfalls also occurs at Nowra, however, as the average annual rainfall at Nowra is about $1\frac{1}{2}$ times that recorded at Braidwood, the average monthly rainfalls are substantially greater, the maximum being nearly four inches in the summer months and about $2\frac{1}{2}$ inches in the winter months.

9. PERSISTENCE OF STREAMFLOWS.

Flows in the majority of streams in the Shoalhaven River Valley tend to continue for significant periods of time after the cessation of rainfall. The conclusion which may be drawn from this is that contributions to streamflow from groundwater are relatively high and of extended duration.

A procedure commonly employed to enable comparison of streamflow persistence to be made between stations is the preparation of graphs showing flow duration curves. These curves indicate the cumulative percentages of time that discharges have varied from the minimum flow, which in many instances is zero, up to the maximum discharge or any other selected flow. Flow duration curves are constructed to show the percentages of time that flows were equal to or greater than (or alternatively equal to or less than) any selected discharge. The flow duration curves and data given in this report correspond to the percentages of time that flows were equal to or greater than any selected flow.

The flow duration curve of the Mongarlowe River at Marlowe is given at Figure 21 and the frequencies of flow at this station are given in the following Table 12.

TABLE 12.

Percentage of Time Flow Equalled or Exceeded	Corresponding Flows	
	Cusecs	Gallons Per Minute
10	385	144,000
30	114	42,700
50	50	18,700
70	22	8,200
90	8	3,000
95	5	1,900
100	2	700

The duration curve of discharge for the Corang River at Hockeys is shown at Figure 22 and the flow frequency statistics for this station are given in the following Table 13.

TABLE 13.

Percentage of Time Flow Equalled or Exceeded	Corresponding Flows	
	Cusecs	Gallons Per Minute

Whilst the flow duration curves shown at Figures 21 to 25 indicate the frequency of various flows at the particular stations they do not permit a comparison to be made of the relative flow duration characteristics of the various sub-catchments in the valley.

To enable these comparisons to be made, the flow duration curves for the five stations have been replotted in the form of duration curves of flow per square mile of catchment area and are shown at Figure 26.

The curves shown at Figure 26 indicate that, of the five selected stations the Kangaroo River at Kangaroo Valley exhibits by far the highest persistence of flow. The high runoff recorded at this station is attributed to the high average annual rainfall of nearly sixty inches over the catchment and the relatively steep topography of the Kangaroo Valley.

The duration curves of flow per square mile for the Endrick River at Nowra Road and the Mongarlowe River at Marlowe are very similar. This result is to be expected as the catchments are located in relatively close proximity to each other and have generally similar topography.

The catchment of the Corang River at Hockeys is situated between the Endrick and Mongarlowe River catchments and could therefore be expected to provide similar flow persistence characteristics per unit area of catchment. However as indicated at Figure 26 flow frequencies of the Corang River at Hockeys are substantially below those of the other adjoining catchments. This difference in flow characteristics is attributable to the different periods of record available for the three stations, the flow frequencies for the Corang River at Hockeys being based on 42 years of record, whereas the frequencies for the Endrick River at Nowra Road and the Mongarlowe River at Marlowe are based on 13 years and 21 years respectively.

The duration curve of discharge for the Shoalhaven River at Welcome Reef is substantially below those of all the other selected stations. However as the catchment area above Welcome Reef is more than six times greater than any of the other catchments studied and as yields normally decrease as the catchment area increases, this result is to be expected.

10. OCCURRENCE OF FLOODING.

Major floods are not of frequent occurrence in the Shoalhaven River Valley. Upstream of Nowra there are no major centres of population located on the Shoalhaven River and any flooding which has occurred in towns in the upper Shoalhaven Valley is due to localised runoff.

Flooding of the low lying areas near Nowra has occurred as a result of local heavy rainfall in association with minor floods in the Shoalhaven River. However, medium and major floods at Nowra are mainly due to flood runoffs from the upper Shoalhaven River catchment. Below Nowra flood heights are influenced by the timing of the flood hydrograph in relation to tidal behaviour.

The distribution and magnitudes of flood heights greater than fifteen feet (equivalent to a discharge of about 22,000 cusecs), which have been recorded for the Shoalhaven River at Welcome Reef over the period from 1909 to 1966, are indicated at Figure 27. The highest recorded flood at this location occurred in May, 1925 when the river reached a maximum gauge height of 55 feet 6 inches. The estimated corresponding peak discharge at this station was 313,000 cusecs which is equivalent to a runoff of nearly 300 cusecs per square mile.

No records are available for the May, 1925 flood for the gauging stations at Nowra Road, Marlowe or Kangaroo Valley. The estimated maximum discharge of the Corang River at Hockeys during this flood was about 17,000 cusecs which is only the fourth highest flood recorded at this location since 1924.

The second highest flood recorded at Welcome Reef occurred in October, 1959 when a peak height of 42 feet 2 inches was recorded. The estimated discharge of 164,000 cusecs corresponding to this height is little more than half of the maximum May, 1925 discharge. Maximum discharges recorded during the October, 1959 flood at other gauging stations in the valley were of major magnitudes. At the stations located on the Mongarlowe River at Marlowe and the Kangaroo River at Kangaroo Valley the October, 1959 flood was the highest recorded over the periods of available records.

Details of the eight highest floods recorded for the Shoalhaven River at Welcome Reef from 1909 to 1966 are given in the following Table 17.

TABLE 17.

Month	Maximum Flood Height	Estimated Maximum Flow (Cusecs)
May 1925	55 ft. 6 ins.	313,000
October 1959	42 ft. 2 ins.	164,000
October 1916	40 ft. 0 ins.	130,000
April 1945	37 ft. 0 ins.	124,000
May 1943	31 ft. 3 ins.	85,000
June 1952	30 ft. 1 ins.	78,500
July 1959	30 ft. 0 ins.	78,000
July 1922	29 ft. 0 ins.	72,000

Because of the damage which has been occasioned by past floods, the Shoalhaven Shire Council is at present undertaking a programme of works (with 80 percent of the finance being provided by the Commonwealth and State Governments in equal shares), designed to reduce inflow of floodwaters to low lying land and to improve drainage of floodwaters during the falling stages of a flood. The works comprise a system of low levees, drains and flood gates in the flood liable areas downstream of Nowra.

11. DROUGHT PERIODS.

There does not appear to be any specific definition of the term "drought". Generally it is considered to be an extended period of low rainfall at any location. However the criteria used in assessing if an area is under drought conditions vary with geographical location, average rainfall and normal crop requirements. For example a continuous period of twelve months with low rainfalls may be considered to be a drought on a coastal catchment whereas such rainfalls may be considered to be normal on an inland catchment.

In general an area is considered to be under drought conditions when the soil moisture is insufficient for the requirements of the majority of crops during the growing season or when water shortages for domestic, industrial or municipal purposes are experienced. A prime indicator of drought conditions is a diminished or exhausted rate of streamflow.

Graphs showing average annual rainfalls at Robertson and Nowra and at Mount Fairy and Braidwood are given at Figures 28 and 29 respectively. These graphs indicate that the lowest calendar year rainfalls at Braidwood and Nowra were 15.47 inches and 20.62 inches in 1944 and 1895 respectively. In addition the graphs show that the longest period of below average rainfall at the majority of the stations appeared to occur from about 1901 to 1911 and this would seem to be the most critical drought period for the Shoalhaven Valley since records commenced in 1887 at Braidwood.

However, a second period of low rainfall occurred from about 1935 to 1944 and this period was almost as severe particularly in coastal sections of the valley. As indicated at Figures 28 and 29 other shorter periods of

below average rainfall have occurred but these have been alleviated somewhat by above average rainfalls during preceding or following years.

A feature of the annual rainfall graphs is the relative reliability of rainfall at Robertson (Figure 28). In addition to the high average rainfall of nearly 64 inches, years of below average rainfall do not extend for significant periods, the longest period of below average rainfall being only about six years (1905 - 1910). However, during this six year period the average rainfall was about 45 inches which was so distributed during the period to be adequate for most agricultural purposes.

Since the commencement of regular recording of streamflows of the Mongarlowe River at Marlowe in 1945 the minimum twelve monthly flow occurred from October, 1964 to September, 1965 and was 16,400 acre feet. This flow corresponds to only 9 percent of the average annual discharge at this station.

At the gauging station located on the Corang River at Hockeys the minimum flow during a twelve month period was only 3,100 acre feet (from March, 1941 to February, 1942) or 5 percent of the average annual flow recorded at this location since 1924.

The minimum twelve monthly discharge of the Endrick River at Nowra Road since 1953 was about 7,100 acre feet from October, 1964 to September, 1965. This discharge corresponds to about 7 percent of the average annual flow.

The gauging station located on the Kangaroo River at Kangaroo Valley was established in July, 1954 and since that date the minimum twelve monthly flow was about 24,000 acre feet from September, 1964 to August, 1965. As the average annual flow at this station is of the order of 230,000 acre feet the minimum twelve monthly flow corresponds to about 11 percent of the average.

Over the period of available records from 1909 for the Shoalhaven River at Welcome Reef the lowest flow over any period of twelve successive months has been 37,100 acre feet from December 1939 to November 1940 as compared with the flow of 85,500 acre feet from February 1965 to January 1966. These flows are equivalent to only 8 percent and 18 percent respectively of the average annual flow.

The minimum twelve monthly flows at selected stations in the Shoalhaven River Valley and their percentages of the respective average annual flows at the stations are given in the following Table 18.

TABLE 18.

Stream	Station	Minimum Twelve Monthly Flow		
		Period	Acre Feet	Percentage of Mean Annual Flow
Mongarlowe River	Marlowe	Oct. 1964 to Sept. 1965	16,400	9%
Corang River	Hockeys	March 1941 to Feb. 1942	3,100	5%
Endrick River	Nowra Road	Oct. 1964 to Sept. 1965	7,100	7%
Kangaroo River	Kangaroo Valley	Sept. 1964 to Aug. 1965	24,000	11%
Shoalhaven River	Welcome Reef	Dec. 1939 to Nov. 1940	37,100	8%

As previously indicated, streamflows in the Shoalhaven River Valley are relatively persistent. An indication of this persistency can be obtained by consideration of periods of zero flow, if any, recorded at each gauging station.

Over the period of available records for the Shoalhaven River at Welcome Reef from 1909 to date there have been several periods of zero flow, the most prolonged being of 76 days duration from December, 1918 to February, 1919. However the total percentage of time during which no flow has occurred at this station is less than one percent.

The longest period of zero flow experienced on the Corang River at Hockeys since 1924 was 97 days from November, 1928 to February, 1929. At this station the total percentage of time during which no flow has occurred is about 3½ percent.

The station on the Endrick River at Nowra Road was established in July, 1953 and since that date there have been only fourteen days of zero flow which corresponds to only about 0.3 percent of the total time.

At the stations located on the Mongarlowe River at Marlowe and on the Kangaroo River at Kangaroo Valley there have been no periods of zero flow over the total periods of record.

The minimum thirty day and sixty day volumes of flow which have been recorded at the five selected stations are shown in the following Table 19.

TABLE 19

Stream	Station	Minimum Recorded Flow (Acre Feet)	
		Thirty Days	Sixty Days
Mongarlowe River	Marlowe	195 (Dec. 1954 to Jan. 1955)	452 (Dec. 1954 to Jan. 1955)
Corang River	Hockeys	0 (Nov. 1928 to Feb. 1929)	0 (Nov. 1928 to Feb. 1929)
Endrick River	Nowra Road	11 (March to April 1965)	77 (Feb. to April 1965)
Kangaroo River	Kangaroo Valley	63 (March to April 1965)	213 (Feb. to April 1965)
Shoalhaven River	Welcome Reef	0 (Dec. 1918 to Feb. 1919)	0 (Dec. 1918 to Feb. 1919)

As indicated in Table 19 the minimum thirty and sixty day volumes recorded on the Endrick River at Nowra Road and the Kangaroo River at Kangaroo Valley occurred during 1965. However these stations were not established until 1953 and 1954 respectively and therefore the records do not cover earlier critical drought periods.

12. THE 1964-1966 DROUGHT.

From late 1964 to early 1966 a period of extremely low rainfall was experienced in the Shoalhaven River Valley. At Nowra the twelve monthly rainfall from October, 1964 to September, 1965 inclusive was 21.90 inches which is about 43 percent greater than the minimum rainfall over a twelve month period recorded at this location since 1896.

The minimum twelve monthly rainfall at Braidwood during the 1964-1966 drought was 14.23 inches from September, 1964 to August, 1965, this rainfall being about 33 percent greater than the minimum twelve monthly rainfall recorded over a period of 80 years.

The recorded monthly rainfalls at Braidwood, Robertson and Nowra over the period from July, 1964 to June, 1967 are shown in Table 20.

TABLE 20

Month		Rainfall (Points)		
		Braidwood	Robertson	Nowra
July	1964	201	84	46
August	1964	291	282	216
September	1964	174	200	146
October	1964	399	378	300

December	1965	276	487	386
January	1966	81	145	84
February	1966	374	846	313
March	1966	146	898	298
April	1966	13	124	39
May	1966	91	61	29
June	1966	335	1,044	626
July	1966	118	142	106
August	1966	152	282	133
September	1966	261	427	215
October	1966	393	585	451
November	1966	598	2,101	857
December	1966	746	449	345
January	1967	321	793	588
February	1967	44	300	161
March	1967	159	772	257
April	1967	26	135	91
May	1967	106	153	83
June	1967	158	1,365	535
Totals October 1964 to September 1965		1,528	3,178	2,190
Totals July 1964 to June 1967		7,257	16,253	9,030

Critically low flows of extended duration were experienced in streams in the Shoalhaven River Valley during the years 1964 to 1966. The minimum twelve monthly flows recorded at the stations at Marlowe, Hockeys, Nowra Road, Kangaroo Valley and Welcome Reef are shown in the following Table 21.

TABLE 21.

Stream	Station	Minimum Twelve Monthly Flow During 1964-66 Drought		
		Period	Acre Feet	Percentage of Mean Annual Flow
Mongarlowe River	Marlowe	Oct. 1964 to Sept. 1965	16,400	9%
Corang River	Hockeys	Dec. 1964 to Nov. 1965	3,200	5%
Endrick River	Nowra Road	Oct. 1964 to Sept. 1965	7,100	7%
Kangaroo River	Kangaroo Valley	Sept. 1964 to Aug. 1965	24,000	11%
Shoalhaven River	Welcome Reef	Feb. 1965 to Jan. 1966.	85,500	18%

Comparison of the twelve monthly discharges shown in the foregoing Table 21 with the minimum twelve monthly flows given in Table 18 in Section 11 shows that over a twelve month period the discharges recorded at Marlowe, Nowra Road and Kangaroo Valley during the 1964-1966 drought were the lowest recorded since commencement of records at these locations.

In addition the minimum 1964-1966 drought period discharge over twelve months at Hockeys was about 3,200 acre feet or only about 100 acre feet greater than the minimum recorded at this location since 1924. However the minimum twelve monthly flow of the Shoalhaven River at Welcome Reef during the 1964-1966 drought was more than double the minimum flow of 37,000 acre feet recorded during the years 1939-1940.

All streams in the valley experienced extremely low or zero flows during the 1964-1966 drought period. A schedule of the minimum thirty day and sixty day discharges at Marlowe, Hockeys, Nowra Road, Kangaroo Valley and Welcome Reef is given in Table 22.

TABLE 22.

Stream	Station	Minimum Total Flow During 1964 - 1966 (Acre Feet)	
		Thirty Days	Sixty Days
Mongarlowe River	Marlowe	250	1,080
Corang River	Hockeys	0	3
Endrick River	Nowra Road	11	77
Kangaroo River	Kangaroo Valley	63	213
Shoalhaven River	Welcome Reef	1,750	4,500

Comparison of Table 22 with Table 19 given in Section 11 shows that, with the exception of the station at Welcome Reef, minimum thirty and sixty day flows during the 1964-1966 drought, either equalled or approached the minimum corresponding discharges recorded at all the stations.

The 1964-1966 drought conditions were alleviated by the occurrence of above average rainfalls in October, 1965 when over six, seven and twelve inches were recorded at Braidwood, Nowra and Robertson respectively. Additional above average rainfalls occurred in December, 1965 and February, 1966 and resulted in appreciable increases in flows in all streams in the valley.

Since February, 1966, rainfall in the Shoalhaven Valley has been adequate for most agricultural purposes. Details of recent streamflow measurements obtained at the gauging stations located at Marlowe, Hockeys, Nowra Road, Kangaroo Valley and Welcome Reef are given in the following Table 23.

TABLE 23.

Stream	Station	Date of Measurement	Measured Flow (Cusecs)
Mongarlowe River	Marlowe	29.5.1967	18
Corang River	Hockeys	29.5.1967	3
Endrick River	Nowra Road	29.5.1967	5
Kangaroo River	Kangaroo Valley	1.6.1967	23
Shoalhaven River	Welcome Reef	29.5.1967	79

13. WATER REQUIREMENTS FOR CURRENT DEVELOPMENT.

Intensive dairying in the coastal section of the valley and the grazing of sheep for wool and mutton in the inland sections are the main rural activities in the Shoalhaven River Valley; secondary rural activities are the growing of fodder and the grazing of cattle. Currently the biggest industrial use is by the Wiggins Teape Shoalhaven Paper Mill which has a daily water requirement of about $3\frac{1}{2}$ million gallons.

The area authorised for irrigation under the Water Act has increased from 333 acres at June, 1945 to about 3,100 acres at June, 1967 and the total number of irrigation licenses has increased from 18 in 1945 to 118 in 1967. The area presently authorised for irrigation is by far the greatest area licensed in the Shoalhaven River Valley, being some 600 acres above the next highest licensed area of 2,500 acres in 1959. The variation in the total number of irrigation licenses and corresponding areas over the period from June, 1945 to June, 1967 is shown at Figure 30.

The average area per license has remained relatively constant at about 20 acres since 1945, and at June, 1967 was 27 acres per license.

Whilst there are no major water conservation or flood mitigation storages constructed in the Shoalhaven River Valley there are a number of minor storages constructed for town water supp'y purposes.

The Wingecarribee Shire Council has constructed a concrete arch dam of maximum height 100 feet over Bundanoon Creek. This storage, which was completed in 1959, has a maximum capacity of 450 million gallons (1,650 acre feet) and provides water supplies to Moss Vale, Bundanoon, Exeter, Berrima and Sutton Forest.

The Shoalhaven Shire Council has constructed two minor dams for water supply purposes in the coastal section of the valley. The largest of these storages, which is located on Flat Rock Creek, retains a maximum storage volume of 140 million gallons (515 acre feet). The other storage is the Cambewarra Dam with a maximum capacity of about 9 million gallons (33 acre feet).

In addition the Shoalhaven Shire Council pumps water from the Shoalhaven River at Burrier for domestic and industrial purposes, the maximum pumping rate being 7,300 gallons per minute. The Shoalhaven Shire Council proposes to construct a storage of capacity 2,300 million gallons (8,500 acre feet) on Danjera Creek near Yalwal for water supply purposes.

Water supply for the town of Braidwood is obtained by pumping at a rate of 200 gallons per minute from the Shoalhaven River at a point about 4½ miles west of the town. The town of Kangaroo Valley has been similarly provided with water supplies by pumping from the Kangaroo River (the works being completed in October 1956) at a maximum rate of 500 gallons per minute.

The estimated maximum requirements in the Shoalhaven River Valley under present conditions for irrigation under license, water supply and riparian usage (not including transmission losses) are given in Table 24.

TABLE 24.

Requirement	Cusecs	Acre Feet per Annum
Irrigation under license (3,140 acres at 2 feet per 8 month season)	13	9,500
Town, commercial and stock water supplies	48	35,000
Riparian usage	51	37,200
Totals	112	81,700

As indicated in Table 24 there is a limited demand for irrigation in the Shoalhaven River Valley, the irrigation demand representing only about nine percent of the estimated maximum total demand exclusive of transmission losses.

The areas authorised for irrigation on the Shoalhaven River and its tributaries at 30th June, 1967 and the estimated total demands for each tributary and selected sections of the Shoalhaven River (including town and industrial water supplies and riparian usage but excluding transmission losses) are shown in Table 25.

TABLE 25.

Stream	Area Authorised for Irrigation at 30th June, 1967 (Acres)	Total Demand	
		Cusecs	Acre Feet per Annum
Brundee Swamp	20	0.5	370
Flat Rock Creek	-	1.5	1,100
Barringella Creek	17	0.2	140
Broughton Creek	432	3.8	2,800
Bomaderry Creek	70	2.5	1,800
Bugong Creek	60	0.5	370
Kangaroo River	1,718	16.6	12,100
Joarima Creek	-	0.8	580
Bugonia Creek	8	1.2	880
Shoalhaven River below Endrick River	55	46.3	33,800
Endrick River	-	4.0	2,900
Bindee Brook	21	0.4	290
Mongarlowe River	75	4.7	3,400
Shoalhaven River between Mongarlowe and Endrick Rivers	-	1.6	1,200
Corang River	20	1.4	1,000
Bombay and Gillamatong Creeks	47	1.4	1,000
Jembaiicumbe Creek	15	0.5	370
Shoalhaven River below Jembaiicumbe Creek to Mongarlowe River	575	21.1	15,400
Shoalhaven River above Jembaiicumbe Creek	10	3.0	2,200
Totals	3,143	112.0	81,700

The foregoing requirements given in Table 25 do not include any allowance

for transmission losses due to evaporation from the stream surface and seepage into the bed and banks of each channel. These losses, which can be of substantial magnitudes particularly during drought periods, are related to flow levels in the stream channels and groundwater conditions and therefore can be expected to vary widely depending on antecedent meteorological conditions.

14. POSSIBLE IRRIGATION DEVELOPMENT.

Provision of an assured water supply would enable the present production of vegetables, pasture and fodder crops to be increased by more intensive irrigation.

The areas which appear suitable for irrigation have been determined with the assistance of aerial photographs. The extent of areas assessed as suitable for irrigation is summarised in Table 26 below:-

TABLE 26

Name of Stream	Assessed Area Suitable for Irrigation (Acres)
Shealhaven River:	
Above Jembajicumbene Creek confluence	3,300
Junction Jembajicumbene Creek to junction Mengarlowe River	1,950
Junction Mengarlowe River to junction Endrick River	100
Junction Endrick River to limit of tidal influence	50
Limit of tidal influence to Nowra	1,400
Below Nowra	4,500
Tributaries of Shealhaven River:	
Crookhaven Creek	1,500
Jembajicumbene Creek and tributaries	3,700
Bombay Creek and tributaries	800
Gillamateng Creek	2,400
Durran Durra Creek and tributaries	1,100
Reedy Creek and tributaries	2,300
Bere Creek and tributaries	1,500
Mengarlowe River	800
Cerang River and tributaries	600
Kangaree River and tributaries	3,400
Bomaderry Creek and tributaries	700
Broughton Creek and tributaries	4,600
Remaining tributaries	5,300
TOTAL	40,000

A factor which could govern the extent and rate of irrigation development is the unfavourable distribution of suitable and irrigable areas. Of the total area of 40,000 acres assessed as being suitable for irrigation, approximately 6,000 acres lie within the tidal influence which extends 30 miles upstream from the coast to Burrier. Effective development of irrigation in this area would be dependent upon the provision of a fresh water supply by construction of barrages on the lower river or by conveyance of water to the irrigable areas by pipeline.

Due to the nature of the main river channel construction of a barrage on the river proper would be extremely costly and would introduce flood drainage and navigational difficulties.

Considerable areas on the Shoalhaven River below Nowra and on Broughton and Crookhaven Creeks are flood liable. Because of the nature of the drainage

pattern within the Shoalhaven Catchment, a significant proportion of the areas suitable for irrigation lie on smaller streams which command only minor catchments possessing limited streamflow potential.

15. INVESTIGATION OF STORAGE PROPOSALS.

When consideration was initially given to the construction of a major storage dam on the Shoalhaven River it was envisaged as a multi-purpose project including not only the provision of water for irrigation but also for the town of Nowra and other centres of population. In addition there also exists a considerable potential for hydro-electric power generation.

This situation led to the constitution of the Shoalhaven River Water Supply Investigation Committee in 1947 for the purpose of investigating and reporting upon proposals for the utilisation of water from the Shoalhaven River.

The Committee recommended that the then five local Councils in the Shoalhaven Area should consider a district water supply scheme with the Shoalhaven River as the main source of supply. Such a scheme was approved by the Shoalhaven Shire Council shortly after its inauguration in 1948.

This Committee, during the period 1947-52, gave consideration to a scheme involving the construction of a storage dam at Devil's Bridge (or alternatively Welcome Reef), subsidiary storages on the Endrick and Corang Rivers, a tunnel 19 miles in length to the head of Conjola Creek together with the necessary balancing storage, pressure pipes to power stations and gravitation mains to service reservoirs. The scheme also envisaged the reticulation of water to hydro-electric generating stations and to towns and farms on the coastal strip between Kiama and Ulladulla.

The Committee, in its investigations, paid regard to the expected economics of hydro-electric power generation together with the likely revenue from water in the Local Government areas of Nowra, Cambewarra, Ulladulla, Clyde, Berry, Broughton Vale, Gerringong, Kiama, Jambaroo, Shellharbour, North Illawarra and Wollongong. (These areas later became the Shoalhaven Shire, Kiama and Shellharbour Municipalities and the City of Greater Wollongong).

In addition the Committee carried out an economic survey of the area and as a consequence concluded that with some irrigation on each farm and a dependable stock water supply, an appreciable increase in production and a stabilisation of the dairy industry might be expected.

Although consideration was given at the time to the possibility of sharing the cost of storage with the Metropolitan Water Sewerage and Drainage Board, the Board did not have any immediate need for water from the Shoalhaven River. However by 1960 the Board found it necessary to consider the means by which the demand of the rapidly growing Illawarra District could be supplemented and, having concluded that the Shoalhaven Valley was the obvious future source of supply, asked the Government to reconvene the Committee. This was done in September 1960.

In October, 1963 the Committee submitted its report to the Minister for Conservation concluding amongst other things that, provided adequate water supplies were reserved for stock and licensed irrigation purposes, the aspect of greatest importance in the development of the surface water resources of the Shoalhaven Valley is the provision of supplies to meet the present and future domestic and industrial needs of the valley and the rapidly expanding Illawarra District. Broadly the Committee recommended that the Metropolitan Water Sewerage and Drainage Board should be permitted to divert some water subject to suitable provision being made for:

- (a) stock and domestic water supplies;
- (b) town water supplies other than those in the Shoalhaven Shire;
- (c) areas irrigated from pumps licensed under Part II of the Water Act;
- (d) special requirements of the Shoalhaven Shire due to a contractual obligation to a paper mill.

In respect of the requirements of the Metropolitan Water Sewerage and Drainage Board, the Investigating Committee concerned itself primarily with the South Coast area on the basis that the Board's allocation of water from the Shoalhaven Valley to meet its requirements in the Sydney Metropolitan Area would be subsequently recommended by a future Committee. The Board's investigations have confirmed that the increasing metropolitan requirements could necessitate substantial utilisation of water from the Shoalhaven River.

The Commission's long term programme envisages construction of storages for irrigation and domestic and stock purposes at an estimated cost of \$12 million on the upper Shoalhaven and Endrick Rivers (the approximate locations of these and other dam sites previously considered are indicated at Figure 31).

Selection of the actual storage sites has not yet been made by the Commission. Before this is possible, a thorough examination of the river valley will be essential followed by detailed investigation of potential storage sites.

The Metropolitan Water Sewerage and Drainage Board (utilising the services of the Snowy Mountains Hydro-Electric Authority) is investigating proposals for augmentation of the Board's whole storage and distribution system so as to provide for domestic and industrial supplies for its South Coast and Sydney Metropolitan Areas. These investigations are being undertaken in respect of proposals both in the Board's area of operations and in the Shoalhaven Valley.

In August, 1966 the Premier approved the constitution of the Shoalhaven River Water Supply Standing Committee to comprise representatives of the Water Conservation and Irrigation Commission (as Chairman and Convenor), Department of Public Works, Metropolitan Water Sewerage and Drainage Board and Electricity Commission for the purpose of reviewing from time to time the manner in which the water resources of the Shoalhaven River should be utilised in the best interests of the State. This Committee would consider any proposals for the use of Shoalhaven waters referred by the Minister for Conservation, including those arising from current investigations by the Metropolitan Water Sewerage and Drainage Board.

16. ACKNOWLEDGMENT.

The Water Conservation and Irrigation Commission gratefully acknowledges the assistance provided by the Director, Bureau of Meteorology, in supplying the section on Climatic Features, the Rainfall Statistical Data and the Median Rainfall Maps for inclusion in this report, the New South Wales Department of Public Works in providing details of the various town water supply schemes and the Metropolitan Water Sewerage and Drainage Board in supplying details of stream gauging stations and information concerning investigation of storage proposals.

MONGARLOWE RIVER AT MARLOWE.

LOCATION: Latitude $35^{\circ}16'$ Longitude $149^{\circ}55'$

PERIOD OF ESTABLISHMENT: August 1945 to date.

COMPLETE YEARS OF COMPUTED RECORDS: 21

ZERO OF GAUGE: R.L. 45.04 Assumed Datum.

CATCHMENT AREA: 175 Square Miles.

CONTROL: Rock Bar.

EQUIPMENT: Automatic Recorder (Float Type) installed January 1954.
Staff Gauge, range 0 to 30 feet.

CURRENT METER OBSERVATIONS:

(a) Number obtained	:	131
(b) Maximum observation in cusecs	:	2,928
(c) Minimum observation in cusecs	:	3.2

MAXIMUM ESTIMATED DISCHARGE DURING PERIOD OF RECORDS: 47,200 cusecs.

MEAN DAILY DISCHARGE FOR 21 YEARS: 237 cusecs.

MEAN ANNUAL DISCHARGE FOR 21 YEARS: 173,000 acre feet.

SHOALHAVEN RIVER AT WELCOME REEF

LOCATION: Latitude $35^{\circ}10'$ Longitude $150^{\circ}00'$

PERIOD OF ESTABLISHMENT: June, 1909 to date.

COMPLETE YEARS OF COMPUTED RECORDS: 52

ZERO OF GAUGE: 100.10 Assumed Datum.

CATCHMENT AREA: 1,070 Square Miles.

CONTROL: Rock Bar.

EQUIPMENT: Automatic Recorder (pressure type) installed November 1955 Staff gauge, range 0 to 50 feet.

CURRENT METER OBSERVATIONS:

(a) Number obtained	:	195
(b) Maximum observation in cusecs	:	2,615
(c) Minimum observation in cusecs	:	0.03

MAXIMUM ESTIMATED DISCHARGE DURING PERIOD OF RECORDS: 313,000 cusecs.

MEAN DAILY DISCHARGE FOR 52 YEARS: 640 cusecs.

MEAN ANNUAL DISCHARGE FOR 52 YEARS: 467,000 acre feet.

REMARKS: Periods of missing records computed by correlation with Shoalhaven River at Warri and Mongarlowe River at Charlyong.

CORANG RIVER AT HOCKEYS

LOCATION: Latitude $35^{\circ}09'$ Longitude $150^{\circ}02'$

PERIOD OF ESTABLISHMENT: September 1924 to date.

COMPLETE YEARS OF COMPUTED RECORDS:

42

ZERO OF GAUGE: R.L. 1780.23 Water Conservation Datum.

CATCHMENT AREA: 62 Square Miles.

CONTROL: Rock Bar.

EQUIPMENT: Automatic Recorder (Pressure type)
installed August, 1926.
Staff Gauge, range 0 to 25 feet.

CURRENT METER OBSERVATIONS:

(a) Number obtained : 261

(b) Maximum observation
in cusecs : 1,700

(c) Minimum observation
in cusecs : 0

MAXIMUM ESTIMATED DISCHARGE DURING PERIOD OF RECORDS:

34,700 cusecs

MEAN DAILY DISCHARGE FOR 42 YEARS:

80 cusecs.

MEAN ANNUAL DISCHARGE FOR 42 YEARS:

58,100 acre feet

ENDRICK RIVER AT NOWRA ROAD

LOCATION: Latitude $35^{\circ}05'$ Longitude $150^{\circ}07'$

PERIOD OF ESTABLISHMENT: July, 1953 to date.

COMPLETE YEARS OF COMPUTED RECORDS: 13

ZERO OF GAUGE: R.L. 1747.88 Water Conservation Datum.

CATCHMENT AREA: 81 Square Miles.

CONTROL: Concrete Causeway.

EQUIPMENT: Automatic Recorder (Float Type)
installed November 1953.
Staff Gauge, range 0 to 20 feet.

CURRENT METER OBSERVATIONS:

(a) Number obtained :	125
(b) Maximum observation in cusecs :	2,836
(c) Minimum observation in cusecs :	0

MAXIMUM ESTIMATED DISCHARGE DURING PERIOD OF RECORDS: 28,000 cusecs.

MEAN DAILY DISCHARGE FOR 13 YEARS: 143 cusecs.

MEAN ANNUAL DISCHARGE FOR 13 YEARS: 105,000 acre feet.

ENDRICK RIVER AT NOWRA ROAD.

KANGAROO RIVER AT KANGAROO VALLEY

LOCATION: Latitude $34^{\circ}44'$ Longitude $150^{\circ}31'$

PERIOD OF ESTABLISHMENT: July, 1954 to date.

COMPLETE YEARS OF COMPUTED RECORDS: 9.

ZERO OF GAUGE: R.L. 38.31 Assumed Datum.

CATCHMENT AREA: 93 Square Miles.

CONTROL: Rock Bar.

EQUIPMENT: Staff gauge, range 0 to 50 feet.

CURRENT METER OBSERVATIONS:

(a) Number obtained	:	102
(b) Maximum observation in cusecs	:	15,120
(c) Minimum observation in cusecs	:	0.8

MAXIMUM ESTIMATED DISCHARGE DURING PERIOD OF RECORDS: 81,000 cusecs.

MEAN DAILY DISCHARGE FOR 9 YEARS: 310 cusecs.

MEAN ANNUAL DISCHARGE FOR 9 YEARS: 227,000 acre feet.
